### 3.1 INTRODUCTION

Compartmental or mixing-cell models have been applied to groundwater flow systems by a number of investigators. Note that the expressions "compartment", "cell" and "mixing cell" are synonymous and used interchangeably in this paper. The compartmental model represents the groundwater system as a network of interconnected cells or compartments through which water and one or more dissolved constituents (tracers) are transported. Within a given cell, perfect or complete mixing of the tracer occurs, although some models relax this constraint. Flow rates of water and tracer between cells can be calculated by:

- 1) use of a flow model that solves the partial differential equations of groundwater flow
- 2) calibration with observed tracer data
- 3) a flow algorithm based on linear or non-linear reservoir theory, or
- 4) some combination of the preceding.

Each cell in the model depicts a region of the hydrogeological system; regions are differentiated based upon their hydrogeological uniformity, the availability of data, the degree of resolution desired, and constraints imposed by numerical solutions.

Compartmental models have been used to solve the inverse problem (estimating aquifer properties and recharge boundary conditions) (Adar and Neuman 1986; 1988; Adar et al. 1988; Adar and Sorek 1989; 1990). Other applications have sought to determine groundwater ages and residence times (Campana 1975; 1987; Campana and Simpson 1984; Campana and
