ABSTRACT

Reservoir computing is a neuromorphic architecture that potentially offers viable solutions to the growing energy costs of machine learning. The majority of neuromorphic computing is currently software-based, where neural network properties and performance can be reconfigured to suit different computational tasks. This critical functionality is missing in "physical" reservoir computing schemes that exploit nonlinear and history-dependent memory responses of physical systems for data processing. Here, we experimentally present a 'task-adaptive' approach to physical reservoir computing, capable of reconfiguring key reservoir properties (nonlinearity, memory-capacity and complexity) to optimise computational performance across a broad range of tasks. As a model case of this, we use the temperature and magnetic-field controlled spin-wave response of Cu_2OSeO_3 that hosts skyrmion, conical and helical magnetic phases, providing on-demand access to a host of different physical reservoir responses. We quantify phase-tunable reservoir performance, characterise their properties and discuss the correlation between these in physical reservoirs. This task-adaptive approach overcomes key prior limitations of physical reservoirs, opening opportunities to apply thermodynamically stable and metastable phase control across a wide variety of physical reservoir systems.

Introduction

Physical separation between processing and memory units in the current computer architecture causes significant energy waste due to repeated shuttling of data, known as the von Neumann bottleneck. To circumvent this, neuromorphic computing[1-3], which emulates the brain's neural network to co-locate memory and processor to integrated 'memcomputing' units, has attracted a great deal of attention as a promising future technology for artificial intelligence processing. Reservoir computing[4-7] is a type of neuromorphic architecture with complex recurrent pathways (the 'reservoir') that map input data to a high-dimensional space. Weights within the reservoir are randomly initialised and fixed, and only the small one-dimensional weight vector that linearly connects the reservoir to the output requires optimisation using a computationally-cheap linear regression. As such, reservoir computing can achieve powerful neuromorphic computation at a fraction of the processing cost relative to other schemes, e.g. deep neural network, where the whole (typically more than millions of) weight network must be trained[8].

While reservoir computing was originally conceived in software[4], nonlinear and history-dependent responses of physical systems have also been exploited as reservoirs[9-11]. The field of physical reservoir computing has been rapidly expanding with several promising demonstrations using optical systems[12], analogue electronic circuits[13], memristors[14,15], ferroelectrics[16], magnetic systems[17-21] and even a bucket of water[22]. Skyrmions, topologically non-trivial magnetic whirls, have also been proposed as hosts for reservoir computing[23,24] as part of rapidly growing research efforts towards neuromorphic computing[25-28]. Very recently, there have been a few experimental studies
