

but considerable space would have to be reserved for them. (I mention my dog.) The range of the key values with the alternative formation method is 000000 to 999999. Notice that the range of address values is therefore about one-third, so much less space needs to be reserved. A simple matter such as the order of concatenation can have an enormous effect on the amount of space needed for storing the records. Since the address probably would not have VVV digits, many potential file numbers would still go unused.

The Key Converts to a Probable Address

The reason that considerable space is needed in many situations using the two previous techniques is that the range of acceptable values of keys is much greater than the actual number of keys, so many gaps exist. If we remove most of the empty spaces in the address space, we then have a key space larger than the address space, an example in which social security numbers are the primary keys is illustrated in Figure 1.1.

Note: We have lost the 1-1 correspondence between keys and addresses since we now have more key values than address values.

We need a function then to map the wider range of key values into the narrower range of address values. Such functions, referred to as *hashing functions*, will necessarily map multiple key values into a single address value.

$$\text{hash(key)} \rightarrow \text{probable address}$$

The output of a hashing function generates a *probable address* since we have lost the guarantee of a unique address for every key. This initial probable address for locating a record in a table is also known as the *home address* for the record. Just as its nameake, the food dish, is a "mixing" of ingredients, the hashing function "mixes up" the key value to obtain an address value. Any function that maps the keys into the range of addresses is acceptable but it is desirable if the function also

- Evenly distributes the keys among the addresses.
- Executes efficiently.

The latter guideline is intended to keep the retrieval time to a minimum. The first one is meant to reduce the number of collisions. A *collision* occurs when two distinct

Figure 1.1 Compressed address space.

keys map to the same address. Hashing is then composed of two aspects:

- The function.
- The collision resolution method.

A collision resolution mechanism is necessary when the number of records that map to a given location exceed its capacity. For most of these discussions, we assume an address capacity of one record.

HASHING FUNCTIONS

Key mod N

One of the most popular hashing functions is

$$h(\text{key}) = \text{key mod } N$$

where N is the table size. For positive integers the mod function returns the remainder of dividing the key by N , for example, $17 \text{ mod } 5$ is 2. An advantage of this function is that it returns only values in the range of the address space (0 to $N - 1$).

Key mod P

A variation of the previous function is

$$h(\text{key}) = \text{key mod } P$$

where P is the smallest prime number $\geq N$, the table size. P is then the new table size. Some collision resolution methods require this hashing function.

Truncation

Another class of hashing functions is *truncation* or *subkeying*. If we have social security numbers as the primary keys, for example,

123456789

and wish to map them into a table of 1000 addresses, three digits (not necessarily contiguous) could be used as the address. The function would select which three digits to use. It does not have to be truncation in the usual sense of the word in which the rightmost digits are dropped. The digits may come from any part of the key. Would it be reasonable to truncate the social security number key after the first three digits?
