

Gastroesophageal reflux disease (GERD) is a common condition that occurs when acidic stomach contents enter the esophagus, causing symptoms such as heartburn and regurgitation. GERD can cause inflammation of the esophageal mucosa and slightly increases risk of esophageal cancer.

A healthy esophageal sphincter functions as a valve to keep stomach contents from backing up into the esophagus.

When valve function is reduced, stomach acid can enter the esophagus and cause GERD.

GERD occurs frequently in the presence of hiatal hernia, when part of the stomach moves upward through the diaphragm, causing a reduction in valve function.

Treatment of GERD

GERD is treated with proton pump inhibitor drugs that reduce the production of stomach acid and lifestyle changes such as losing weight and smoking cessation. Some patients may also be considered for a surgical procedure called fundoplication that reinforces the esophageal sphincter.

During fundoplication, the upper part of the stomach is wrapped around the lower part of the esophagus.

The additional resistance prevents stomach content backup.
