

SPECIES & ECOSYSTEM SURVIVAL

Every species plays a crucial role in the health and survival of its ecosystem. From food production to oxygen generation, pollination to seed dispersal, pest control, disease reduction, and waste recycling, each plant, animal and fungi is part of an intricate web of interconnected life.

Species roles are illustrated here using miombo woodland as an example – a forest type found across much of southern Africa.

1 Plants absorb carbon dioxide from the air and release oxygen that animals need to survive. Plants store carbon in their leaves, trunks and roots as well as in the soil around them. This reduces the amount of carbon dioxide entering the atmosphere and therefore helps reduce global warming. Plants help maintain water supplies by moving and releasing moisture, reducing floods and droughts.

2 Plants are a source of food for many animals. This is the basis of food for almost all species in the world. Miombo woodland has elephants and antelopes eat plants and they can become food for predators like lions and wild dogs.

3 Flowering plants need to be pollinated to reproduce. Different species of insects, birds and mammals pollinate different plants. For example bees and moths pollinate baobab trees and many miombo species are pollinated by bats.

4 Many plants rely on animals to disperse their seeds, enabling new plants to grow. For example elephants, primates and birds can knock seeds down the roads, fertilised by their dung, far from the parent plant.

5 Nature recycles everything, with many different species contributing to maintain it. For example, fungi break down dead matter, releasing nutrients back into the soil. Millipedes feed on dead and decaying organic matter and transfer nutrients through their droppings.

8 Every species – including humans – contributes to ecosystem balance. Disturbing this balance can cause some negative consequences. For example, if natural habitat is reduced by humans, strongly invasive like baboons and elephants may threaten existing people's farms, leading to community tensions. Disturbing habitat also increases the risk of disease transfer to humans.

7 There is a constant cycle of life and death, with many species helping dispose of dead matter, keeping the environment clean and healthy. For example vultures dispose of carcasses, helping prevent the spread of diseases like anthrax and rabies.

6 A healthy ecosystem has a balance of predators that keep pest populations under control. For example cheetahs with as leopards and gazels eat herbivores, keeping their populations low. Many reptiles and amphibians reduce the number of insect pests which can be harmful and flow.

Ecosystem Management Mark S. Boyce, Alan W. Haney, 1997-01-01 Until recently natural resource management of such commodities as timber and wildlife was driven largely by the desire to exploit these resources During the past three decades however ecologists have warned that this approach to natural resource management could have unforeseen consequences because it ignored how ecosystems function within the landscape Federal agencies that oversee forest and wildlife resources have begun to implement different schemes of ecosystem management schemes that vary enormously among agencies Contributors to this volume leading experts who are agency personnel as well as researchers now clarify the key elements of sound ecosystem management and offer prescriptions for implementing them The authors discuss definitions of ecosystem management sustainability of ecological systems landscape ecology resource management at different scales and in an ecosystem context new advances in computer technology that facilitate classification schemes for ecosystems ecosystem restoration biological diversity and public concerns Throughout the experts agree that management practices must be sustainable that production of commodities such amenities as recreation and aesthetics and biodiversity must not be allowed to decline over time *Ecosystem Management* Richard Sheppard Mitchell, Charles J. Serpentine Geocology of Western North America Earl B. Alexander, Robert G. Coleman, Todd Keeler-Wolfe, Susan P. Harrison, 2006-11-02 This book is about geology soils and plant communities in serpentine landscapes of western North America Aspects of the interaction of geology and soils reveal a fascinating symbiosis relating the structure composition and distribution of plant communities The plants that survive are a unique group There are some entire genera or even families of plants that are common throughout California that are poorly represented on serpentine while other genera are more diverse on serpentine than on other soils Serpentine rocks have dramatic effects on the vegetation that grows on them Many common plants cannot grow on serpentine soils leaving distinctive suites of plants to occupy serpentine habitats The floristic diversity associated with serpentine soils formed above ultramafic rocks is surprising considering that these soils are toxic to many plants Serpentine barrens of California often look like moonscapes but here we find numerous species of plants of low biomass that produce a richness of species rarely found in the world **Savannas, Barrens, and Rock Outcrop Plant**
