Functional correspondences are known to exist within the brains of both human and non-human primates; however, our understanding of this phenomenon remains largely incomplete. The examination of the topological characteristics inherent in whole-brain functional connectivity bears immense promise in elucidating shared as well as distinctive patterns across different species. In this investigation, we applied topological graph analysis to brain networks and scrutinized the congruencies and disparities within the connectomes of human and marmoset monkey brains. The findings brought to light noteworthy similarities in functional connectivity patterns distributed across the entire brain, with a particular emphasis on the dorsal attention network, default mode network and visual network. Moreover, we discerned unique neural connections between humans and marmosets during both resting and task-oriented states. In essence, our study reveals a combination of shared and divergent functional brain connections underlying spontaneous and specific cognitive functions across these two species.

I. INTRODUCTION

The configuration of functional connections in both the human and non-human primate brains has been shaped by the imperative of energy conservation and the efficient transmission of information [7, 16]. As a remarkably intricate, autonomously organizing, and remarkably energy-efficient biological neural network, the human brain exhibits distinctive patterns of information organization and connectivity when compared to its non-human primate counterparts. These two species share a fundamental reliance on two primary branches of connectivity that underlie their formidable hierarchical computational abilities: structural and functional connectivity. To delve into these properties and discern potential disparities across species, it is essential to quantify and elucidate the intricate topological attributes of the brain, an aspect that has regrettably been largely overlooked in prior research endeavors.

Our pursuit of a deeper understanding of human brain function and related brain disorders is driven by both a fundamental cognitive imperative and clinical necessity, primarily due to our high genetic affinity with non-human primate species [24]. Notably, the great apes exhibit substantial genetic similarities with humans, sharing approximately 99.9% of DNA sequences within the human population, 98.2% with chimpanzees, 97.7% with gorillas, and 96.3% with orangutans. In contrast, monkeys, encompassing macaques and marmosets, share a somewhat lower genetic overlap of approximately 93% [3].

This genetic closeness prompts a fundamental question: to what extent do these shared genetics translate into similar cognitive capabilities? Further, how do the parallels and distinctions observed in the resting and task states between humans and marmosets contribute to cognitive processes? Addressing these inquiries holds significant implications for our comprehension of intelligence across species and its relevance to advancing treatments for

brain diseases [10]. In our quest to tackle these questions, we employ a multidisciplinary approach, drawing on insights from neurophysics, statistical mechanics, computational neuroimaging techniques, and the application of non-invasive functional magnetic resonance imaging (fMRI) for the measurement and mapping of brain connections [18].

Marmosets, in particular, are frequently utilized as preclinical models for studying brain diseases due to the high degree of conservation in brain-related genes between marmosets and humans [24]. Consequently, investigating the intricacies of functional brain similarities and differences between humans and marmosets holds significant interest, as it allows us to discern gaps in cognitive and consciousness functions. Our study focuses on the common marmoset monkey (*Callithrix jacchus*), also known as the white-tufted-ear marmoset, to address these research objectives [15, 20]. It is worth noting that all human and marmoset datasets used in this research are derived from large, publicly accessible open-source repositories, ensuring compliance with international ethical guidelines.

In this study, we harnessed the established cortical networks of both humans and marmosets, conducting a comprehensive comparison of the intricate brain network topologies during resting and task states. This endeavor carries profound implications for enhancing our comprehension of higher-order cognitive capacities.

II. THEORETICAL ANALYSIS

Resting states The human and marmoset resting-state connectome data from the Human Connectome Project [1], which used to map human brain connectivity [19, 22], and the Marmoset Brain Mapping Project [2], which used to map marmoset brain connectivity separately [15, 20].
