oligoclase depositional environments, migrate seaward, setting the stage for the next transgressive phase (Fig. 23). Interfaces between evaporite and oligoclase depositional environments are recorded as accumulations of interbedded evaporite and mudstone (Torres and McLean, 1992; Torres, 1995).

Small oligoclase deposition records (spaced to early transgressive systems tracts). The evaporite platform was wet and characterized by eolian and eolian sedimentation caused mainly from the Federal Lake (center spit) area northwest of the Delaware Basin (July, 1972). Oligoclase sand and silt also migrated along the shelf margins until variable depths (developed and then collapsed) was initiated. These processes probably persisted into the early transgressive phase, during which oligoclase that accumulated on the outer platform were eroded

and transported seaward. Transported largely by turbidity currents, Bone Spring sandstones (mostly sand) were in fact from submarine fans (Fig. 10) similar to those that have been described from outcrop-based studies for the Guadalupian-age Delaware Mountain Group (Gardner, 1992; Barton and Dutton, 1999; Barton and others, 1999). In the subsurface, Bone Spring submarine fans are recognized based on sandstone geometries that are consistent with channel, levee, and other depositional elements (Fig. 10). These fan facies (sandstone) (Barton, 1992) suggest that eolian depositional processes were also important (Fig. 10). (Barton, 1992). Bone-spring sandstones preserved on the shelf likely represent landward remnants eroded by marine processes during transgression.
