ABSTRACT

The FITNET fitness-for-service (FFS) procedure is newly developed to provide rules for the design, fabrication, and flaw (or degradation during the service) assessment aspects of the metallic load-bearing structures with or without welds. The FITNET FFS Procedure provides assessment rules for flaws or damage due to fracture, fatigue, creep and corrosion to demonstrate the structural integrity of the component.

This paper presents validation examples of the fracture module of the FITNET FFS procedure using thin-walled panels with laser beam welded (LBW) stiffeners. The panels were made of high strength aluminum alloys A6013-T6 and A6156-T6. These structure-like laboratory specimens were used to investigate the residual strength behaviour of the fuselage components within the framework of the damage tolerance analysis. The stiffened panels contained two, three and four welded stringers. The stringers oriented in loading direction and panels contained a single center crack artificially introduced between the stringers into the skin material. Additionally, some of the four-stringer panels contained welded clips (short T-joint attachments) located between the stringers. The experimental results of the panels were compared with the predictions of the FITNET FFS procedure. Hence, this paper focuses on the use of this new procedure or the predictions of the critical conditions of these complex thin-walled panels.

The analysis results have shown that the FITNET FFS fracture module can successfully be used for the prediction of the residual strength behaviour of the thin-walled airframe components.

The content of this manuscript was presented at the FITNET final conference, 17-19 May 2006, Amsterdam.

INTRODUCTION

The aircraft fuselage structures are predominantly thin-walled metallic components and damage tolerance behaviours are stringently assessed for postulated or real flaws for fatigue and fracture. Damage tolerance evaluation procedures are partly used to develop optimized inspection and maintenance guidelines for existing structures to operate safely. Furthermore, it provides technically sound remaining life predictions to enhance economic life of the structures while ensuring the safety. Commonly used structural integrity procedures [1-7] are the techniques used to demonstrate the fitness-for-service of engineering components (with and without welds) transmitting loads. FFS procedures have important implications for economic development in assuring the quality of engineered goods and services. Used correctly, they can increase efficiency by preventing over design and unnecessary inspection and repair. Additionally, they can provide a balance between economy and concern for individual safety and environmental protection, where these are affected by component failure. They have been developed and validated using cases of the general engineering structures rather than thin-walled airframe components. However, FFS procedures such as SINTAP [4, 5] and FITNET [8] are of value at the design stage to provide assurance for new constructions, particularly where these may be innovative in the choice of materials or fabrication methods, and at the operation stage to provide assurance throughout the life of the airframe structures.

The application of FFS procedure during the pre-development or design stage of a new aircraft component using a new material or fabrication method (such as welding instead of riveting) can provide significant help for prediction of allowable stresses for a given material, fabrication method and flaw size. Evaluation of the strength and fracture behaviours of the flat technological panels with structural details is of great value, if experimental findings can be predicted using engineering flaw assessment procedures such as FITNET. However, there is a lack
