in the Geological Storage of Carbon Dioxide S. Lombardi, L.K. Altunina, S.E. Beaubien, 2006-01-02 As is now generally
accepted mankind's burning of fossil fuels has resulted in the mass transfer of greenhouse gases to the atmosphere a
modification of the delicately balanced global carbon cycle and a measurable change in world wide temperatures and climate
Although not the most powerful greenhouse gas carbon dioxide CO₂ drives climate change due to the enormous volumes of
this gas pumped into the atmosphere every day Produced in almost equal parts by the transportation industrial and energy
generating sectors atmospheric CO₂ concentrations have increased by about 50% over the last 300 years and according to
some sources are predicted to increase by up to 200% over pre industrial levels during the next 100 years If we are to
reverse this trend in order to prevent significant environmental change in the future action must be taken immediately While
reduced use of fossil fuels through conservation increased efficiency and expanded use of renewable energy sources must be
our ultimate goal short to medium term solutions are needed which can make an impact today Various types of CO₂ storage
techniques have been proposed to fill this need with the injection of this gas into deep geological reservoirs being one of
the most promising For example this approach has the potential to become a closed loop system whereby underground
energy resources are brought to surface their energy extracted via burning or hydrogen extraction and the resulting by
products returned to the subsurface **Proceedings of the Royal Philosophical Society of Glasgow** Royal Philosophical
