

cal sense; however, there are many engineering problems that are far from being an easy mark for the hunter. Most of the problems compiled above are readily accessible to the methods of mathematical analysis because they are linear problems. In many cases the engineer can linearize his problem by means of simplifying assumptions and a mathematical text will easily supply him with all the help he needs. However, if the engineer has a real nonlinear problem, that is, one which loses its sense by linearization, very often he has to grapple with it by himself.

In this paper the attempt is made to give a review of nonlinear problems which are of practical interest and for whose solution methods have been worked out or at least suggested by mathematicians, physicists or engineers. The review is not exhaustive, but it was attempted to include examples of the most typical problems. The question of existence and uniqueness of solutions is only superficially touched; emphasis is laid on methods for obtaining approximate solutions. Many physicists and engineers have the feeling that so-called mathematical proofs of existence and uniqueness of solutions very often merely verify facts which are more or less evident from physical considerations. Unfortunately, in most nonlinear problems physical reasoning is not sufficient or not fully convincing, so that in these cases the questions of existence and uniqueness represent a real challenge to the mathematician. Certain investigations of H. Poincaré and T. Levi-Civita can be mentioned as examples in which mathematical reasoning has virtually extended the range of physical vision. The modern methods of function spaces are likely to make essential contributions to the problem of existence and uniqueness of solutions of nonlinear equations and their boundary problems. Promising steps in this direction have already been made. However, the writer is afraid that this aspect of the subject is beyond his own competency and the scope of this paper.

1. Nonlinear oscillations. General remarks. The theory of mechanical oscillations commonly used in engineering practice is based on the assumption that the restoring forces are proportional to the deflections and the damping forces to the velocities, that is, to the first derivatives of the deflections with respect to time. If we assume constant masses, the equations of motion of an oscillating system are linear, containing as coefficients constant inertia, damping and spring factors. We obtain analogous equations for the oscillations of an electric circuit by assuming constant impedances, that is, by assuming that the network contains only constant reactances, resistances and
