

Flowers

Eventually, the plant will mature and begin to develop buds, which will become flowers.

Flowers may have colours or scents to attract insects and birds.

Pollination

The male part of the flower (anther) releases pollen that must reach the female part (stigma) to become fertilised. Some plants are self-pollinating, while others need birds, animals, insects, or the wind to help move pollen to the stigma.

Pollen fertilises the ovule at the base of the flower to produce fruits that will contain seeds.

Life Cycle of a Flowering Plant

Seeds

Seeds contain a food supply for the development of the tiny plant. They have an outer coat for protecting the seed until germination.

Germination

Every seed contains an embryo that will go onto becoming a plant. Most seeds need water to germinate. The root emerges first and grows down into the soil. A shoot will push up towards the light and will eventually develop into a stem and leaves. Seedlings need water, light, warmth, and nutrients from the soil as they grow into small plants.

Growth

The leaves that unfold use light and carbon dioxide to produce energy for the plant to grow. This process is called photosynthesis.

As the seedling develops, its roots grow into the soil to absorb water and nutrients. Roots help the plant to stay upright as it grows taller.

Did You Know?

The green colour of plant leaves is due to a special pigment called chlorophyll.

Did You Know?

Seeds need to be spread across a large area, away from the parent plant, so they don't need to compete for nutrients, water, and sunlight.
