

- Reliability is good to excellent when raters are experienced but this is difficult to achieve without substantial training
 - semi-structured interview has been developed to increase reliability
- Validity is also good as measured by correlations with other measures of symptom severity, especially those assessing schizophrenia symptomatology
- Given its focus on psychosis and associated symptoms, it is only suitable for patients with fairly significant impairment
- Its use in clinical practice is less well supported, in part because the considerable training is required to achieve the necessary reliability

POSITIVE AND NEGATIVE SYNDROME SCALE (PANSS)

- Developed in the late 1980s to remedy perceived deficits in the BPRS in the assessment of positive & negative symptoms of schizophrenia and other psychotic disorders by adding additional items and providing careful anchors for each
- requires a clinician rater because considerable probing and clinical judgment are required
- A semi-structured interview guide is available
- Reliability for each scale has been shown to be fairly high w/ excellent internal consistency & interrater reliability
- Validity also appears good based on correlation with other symptom severity measures and factor analytic validation of the subscales
- has become the standard tool for assessing clinical outcome in treatment studies of schizophrenia and other psychotic disorders and has been shown to be easy to administer reliably & sensitive to change w/ treatment
- Its high reliability & good coverage of both positive and negative symptoms make it excellent for this purpose
- may also be useful for tracking severity in clinical practice, & its clear anchors make it easy to use in this setting

SCALE FOR THE ASSESSMENT OF POSITIVE SYMPTOMS (SAPS) AND SCALE FOR THE ASSESSMENT OF NEGATIVE SYMPTOMS (SANS)

- SAPS and SANS were designed to provide a detailed assessment of positive and negative symptoms of schizophrenia
 - may be used separately or in tandem
- **SAPS:** assesses hallucinations, delusions bizarre behavior, and thought disorder
- **SANS:** assesses affective flattening, poverty of speech, apathy, anhedonia, and inattentiveness
- Both are mainly used to monitor treatment effects in clinical research

MOOD DISORDERS

HAMILTON RATING SCALE FOR DEPRESSION (HAM-D)

- Was developed in the early 1960s to monitor the severity of major depression with a focus on somatic symptomatology

- **17-item version:** most commonly used version, although versions with different numbers of items, including the 24-item version in Table 5.3-5, have been used in many studies as well
- Was designed for clinician raters but has been used by trained lay administrators as well
- Ratings are completed by the examiner based on the patient interview and observations
- A structured interview guide has been developed to improve reliability
- Ratings can be completed in 15 to 20 minutes
- Reliability is good to excellent, particularly when the structured interview version is used
- Has been used extensively to evaluate change in response to pharmacological and other interventions and, thus, offers the advantage of comparability across a broad range of treatment trials
- It is more problematic in the elderly and the medically ill, in whom the presence of somatic symptoms may not be indicative of major depression

BECK DEPRESSION INVENTORY (BDI)

- Was developed in the early 1960s to rate depression severity, w/ a focus on behavioral and cognitive dimensions of depression
- Current version, the **Beck-II**, has added more coverage of somatic symptoms and covers the most recent 2 weeks
- **Earlier versions:** focused on the past week or even shorter intervals, w/c may be preferable for monitoring treatment response
- Scale can be completed in 5 to 10 minutes
- Test-retest reliability is not consistently high, but this may reflect changes in underlying symptoms
- Validity is supported by correlation with other depression measures
- **Principal use:** as an outcome measure in clinical trials of interventions for major depression, including psychotherapeutic interventions
- Because it is a self-report instrument, it is sometimes used to screen for major depression

ANXIETY DISORDERS

HAMILTON ANXIETY RATING SCALE (HAM-A)

- was developed in the late 1950s to assess anxiety symptoms, both somatic and cognitive
- provides limited coverage of the "worry" required for a diagnosis of generalized anxiety disorder and does not include the episodic anxiety found in panic disorder
- designed to be administered by a clinician, and formal training or the use of a structured interview guide is required to achieve high reliability
- Reliability is fairly good based on internal consistency interrater, and test-retest studies
 - reliability should not be assumed to be high across different users in the absence of formal training
- Validity appears good based on correlation with other anxiety scales but is limited by the relative lack of coverage of domains critical to the modern understanding of anxiety disorders
