Control of Breathing During Exercise Susan A. Ward, 2014-07-01 The control of breathing during exercise remains the source of considerable debate Classical schemes of the exercise hyperpnea have incorporated elements of proportional feed back from chemoreceptor sites carotid body and brainstem and feed forward neurogenic central command and muscle reflex control However the precise details of the control process are still not fully resolved reflecting in part technical and interpretational limitations inherent in isolating putative control mechanisms in the intact exercising human and also the challenges presented by the ventilatory and gas exchange complexities encountered at work rates which engender a metabolic lactic acidosis Although some combination of neurogenic chemoreflex and circulatory coupled processes are likely to contribute to the control intriguingly the overall system appears to evidence considerable redundancy This coupled with the lack of appreciable steady state error signals in the mean levels of arterial PCO₂ PO₂ and pH over a wide range of work rates has motivated the formulation of innovative control models that reflect not only spatial interactions but also temporal interactions i e short term and longer term memory The challenge remains to discriminate between robust control schemes that a integrate such processes within plausible physiological equivalents and b account for both the dynamic and steady state system response over the entire range of exercise intensities Table of Contents Introduction Ventilatory Requirements Ventilatory Responses Ventilatory Control Conclusions References
