Abstract: Evolution is a fundamentally population level process in which variation, drift and selection produce both temporal and spatial patterns of change. Statistical model fitting is now commonly used to estimate which kind of evolutionary process best explains patterns of change through time using models like Brownian motion, stabilizing selection (Ornstein–Uhlenbeck) and directional selection on traits measured from stratigraphic sequences or on phylogenetic trees. But these models assume that the traits possessed by a species are homogeneous. Spatial processes such as dispersal, gene flow and geographical range changes can produce patterns of trait evolution that do not fit the expectations of standard models, even when evolution at the local-population level is governed by drift or a typical OU model of selection. The basic properties of population level processes (variation, drift, selection and population size) are reviewed and the relationship

between their spatial and temporal dynamics is discussed. Typical evolutionary models used in palaeontology incorporate the temporal component of these dynamics, but not the spatial. Range expansions and contractions introduce rate variability into drift processes, range expansion under a drift model can drive directional change in trait evolution, and spatial selection gradients can create spatial variation in traits that can produce long-term directional trends and punctuation events depending on the balance between selection strength, gene flow, extirpation probability and model of speciation. Using computational modelling that spatial processes can create evolutionary outcomes that depart from basic population-level notions from these standard macroevolutionary models.

Key words: Brownian motion, evolutionary model fitting, evolutionary rate, metapopulation, trait evolution.

Evolution is not only a temporal process, but a spatial one. Just as species change through time, they vary in space. Their geographical ranges encompass assorted environmental conditions and harbour considerable genetic and phenotypic variation (Fig. 1). But spatial variation is more than just simple population variation, it is a gradient of differences between local populations or demes that arises from metapopulation population processes related to distance, barriers, gene flow, drift and selection. Spatial variation interacts with evolutionary processes in ways that produce patterns of trait change that differ markedly from the expectations of standard statistical evolutionary models like Brownian motion, directional selection and adaptive peak (Ornstein–Uhlenbeck) models. In this paper, I critically review the ways in which spatial processes cause departures from these standard evolutionary models. My aim is to better inform interpretations drawn from evolutionary model fitting. No existing statistical models fully capture the ways in which spatial processes

modify standard evolutionary models, so no remedies are offered herein; however, the signatures of spatial processes can be recognized in some cases. This paper aims to inform the reader what those signatures might look like in palaeontological data.

Ever since Darwin (1859), variation has been understood to be a central component of evolution. Evolution in its quantitative formulation consists of change in a trait's mean value as a result of the intergenerational sorting effects of drift and selection on the heritable variation within a population (Wright 1929; Fisher 1930; Lande 1976). The Modern Synthesis recognized that rates and directions of evolution are not simply consequences of selection, but are constrained by the size of a population, the amount of variation, and the rate at which variation is replenished by mutation (Fisher 1930; Haldane 1932; Dobzhansky 1937; Huxley 1942). Simpson's (1944) adaptive landscapes with their centrifugal (stabilizing), centripetal (diversifying) and linear (directional) selection

Keywords in Evolutionary Biology Evelyn Fox Keller, Elisabeth Anne Lloyd, 1992 In science more than elsewhere a word is expected to mean what it says nothing more nothing less But scientific discourse is neither different nor separable from ordinary

language meanings are multiple ambiguities ubiquitous Keywords in Evolutionary Biology grapples with this problem in a field especially prone to the confusion engendered by semantic imprecision Written by historians philosophers and biologists including among others Stephen Jay Gould Diane Paul John Beatty Robert Richards Richard Lewontin David Sloan Wilson Peter Bowler and Richard Dawkins these essays identify and explicate those terms in evolutionary biology which though commonly used are plagued by multiple concurrent and historically varying meanings By clarifying these terms in their many guises the editors Evelyn Fox Keller and Elisabeth Lloyd hope to focus attention on major scholarly problems in the field problems sometimes obscured sometimes reveals and sometimes even created by the use of such equivocal words

Competition adaptation and fitness for instance are among the terms whose multiple meaning have led to more than merely semantic debates in evolutionary biology Exploring the complexity of keywords and clarifying their role in prominent issues in the field this book will prove invaluable to scientists and philosophers trying to come to terms with evolutionary theory it will also serve as a useful guide to future research into the way in which scientific language works

Ellen Korsager, 2018-09-05 Firm growth This concept has interested researchers for generations Economists have sought to predict and measure firm growth using a host of different variables while strategic management scholars depict growth as the result of clever analyses and rational resource exploitation Entrepreneurship scholars ever engrossed by successful start ups have pondered why growth sometimes comes fast and sometimes never at all while the field of business history has given countless examples of growing firms in a range of different settings Yet despite research across fields our knowledge of how growth in a firm actually comes about is limited and we still know little about the process This book offers a new reading of economist Edith Penrose s The Theory of the Growth of the Firm The bold statement is that although Penrose s work across fields and generations is amongst the most quoted on firm growth the basic points of her work have yet to be realized and explored empirically Essentially growth is created by a dynamic interrelation between the firm s self conception and its image of context Based on these two subjective categories the firm makes decisions and its actions lead it to develop along a particular path To Penrose this is the basic engine that drives the growth and development of firms This book discusses how the engine of firm growth can be captured in empirical analysis using interpretative theory and narrative methods inspired by recent streams of research in business history
