Abstract

The environmental performance of urban neighbourhoods is a crucial indicator to measure the sustainability of the built urban form, especially as cities face increased urbanisation and densified development. With new construction contributing significantly to global carbon emissions, there is a need to understand how modifications in the urban form can affect its environmental performance at the scale of the neighbourhood. This research addresses this need by developing a Planning Support System workflow to aid decision-making in urban planning in order to analyse environmental performance, focusing on thermal comfort and solar energy potential. It explores the relationship between urban form and the selected environmental performance indicators while utilising freely available 3D geoinformation data of the Netherlands. It develops simplified workflows using established plug-ins and open-source 3D software that can be replicated by smaller municipalities with resource constraints, thus removing barriers to 3D-data based data-driven decision making for sustainable and informed urban planning.

1. Introduction

The built form of urban area significantly affects the environmental performance at the scale of the neighbourhood (Mussawar et al., 2023). Given that construction contributes approximately 40% of the total global carbon emissions, and urbanisation and densification of cities continue unabated, it is necessary to understand the impact of urban form-based decisions on its environmental performance (van Oostrom, 2022). As the scale of action shifts from policy at global level to action at a local level, municipalities are now obliged to create action plans within the realms of the national and international policy (Salter et al., 2020). Acknowledging the critical role of early-stage decision-making in influencing urban form (Méndez Echenagucia et al., 2015), there is a requirement for a Planning Support System workflow that facilitates informed decision-making in planning projects with the objective of analysing environmental performance, as a contribution to sustainability at a local scale.

To derive comprehensive insights into the environmental performance of neighbourhood-scale projects, a 3D perspective is important as buildings exist under the influence of their surroundings. It enables understanding spatial relations from a volumetric viewpoint, highlighting the influence of morphology in immediate surroundings. Thus, this research intends to make use of the freely available 3D geoinformation of the Netherlands to model existing and future scenarios to examine to what extent does change in urban form effect the environmental performance of a neighbourhood.

The environmental performance of buildings and neighbourhoods together contribute to urban liveability as the immediate outdoors are seen as an extension of the living space (Lau et al., 2018). As the research delves into the components and contributors to environmental performance and its measurement, it is crucial to clarify the terminology. Indicators describe the state of the environment and are used to assess performance (European Environment Agency, n.d.). They are often made of a combination of parameters and serve as an estimate of a system, such as PET (thermal comfort indicator) or

Solar Potential estimate derived from solar irradiation (in kWh/m²). Variables are any modifiable factors within a system, such as building orientation, or roof area. They may be dependent or independent in nature and can be measurable or qualitative. Parameters are measurable variables, such air temperature, or percentage of shadowing of roof surfaces.

While multiple performance indicators exist, such as thermal performance, energy consumption, greenery, daylighting, carbon emissions etc, in the context of this research, environmental performance is narrowed down to two performance indicators – the indicator of thermal comfort due to urban built form (estimated using Physiological Equivalent Temperature) and the indicator of solar rooftop energy harvest (using pixel-based Solar Energy Potential suitability analysis). These are selected as both indicators are very dependent on location and morphology and have differing morphological requirements for improvement – as is illustrated further in Table 1.
