Mechanical Properties of Reinforced Thermoplastics D.W. Clegg, A.A. Collyer, 2012-12-06 The reinforcement of

materials such as mud and clay by hair straw and vegetable fibres has been long established in man's history enabling him to improve his buildings and extend his engineering abilities. With the advent of modern synthetic polymers it was rapidly realised that the addition of fibres, flakes and particulate materials to polymer matrices could improve mechanical properties significantly. Fibres and flakes are the most effective and have enabled several polymers with limited properties to compete with long established metallic materials resulting in cost weight and processing economies. This is increasingly apparent in the selection of materials for aerospace and road vehicle applications as well as in a multitude of domestic products. Reinforced plastics, both thermosets and thermoplastics, are used in increasingly harsh environments involving elevated temperatures and aggressive conditions. Fibre reinforcement of thermoplastics dominates and a pattern of increasing replacement of fibre reinforced thermosets by reinforced thermoplastics is emerging. This trend is encouraged by the development of continuous fibre reinforced grades of the newer high temperature engineering thermoplastics such as polyether ether ketone. The first part of this book reviews the mechanical properties and theories of short fibre reinforcement. The principal reinforcements are reviewed and a separate chapter is devoted to the uses of natural fibres as reinforcements for thermoplastics. This is an interesting and commercially important area especially for Third World countries where these fibres are grown but are facing severe competition from synthetic fibres in traditional applications such as ropes and matting.

Mechanical Properties in Progressive Mechanically Processed Metallic Materials Radim Kocich, Lenka Kuncická, 2021-02-24. The demands on innovative materials given by the ever increasing requirements of contemporary industry require the use of high performance engineering materials. The properties of materials and alloys are a result of their structures which can primarily be affected by the preparation/production process. However, the production of materials featuring high levels of the required properties without the necessity to use costly alloying elements or time and money demanding heat treatment technologies typically used to enhance the mechanical properties of metallic materials especially specific strength still remains a challenge. The introduction of thermomechanical treatment represented a breakthrough in grain refinement consequently leading to significant improvement of the mechanical properties of metallic materials. Contrary to conventional production technologies the main advantage of such treatment is the possibility to precisely control structural phenomena that affect the final mechanical and utility properties. Thermomechanical treatment can only decrease the grain size to the scale of microns. However, further research devoted to pushing materials performance beyond the limits led to the introduction of severe plastic deformation (SPD) methods providing producers with the ability to acquire ultra fine grained and nanoscaled metallic materials with superior mechanical properties. SPD methods can be performed with the help of conventional forming equipment; however, many newly designed processes have also been introduced.
